### ABSTRACT

A module  $M$  is called semi-dual continuous if for every submodule  $A$  of  $M$ ,  $M$  decomposes as  $M = M_1 \oplus M_2$  such that  $M_1 \subset A$  and  $M_2 \cap A$  is small in  $M$ . In this note we study the semi-dual continuous abelian groups. The main result is the following: an abelian group  $G$  is semi-dual continuous if and only if  $G$  is torsion and for every prime  $p$ , the primary component  $G_p$  is either of finite rank and divisible, or  $G_p = \Sigma \oplus \langle a_i \rangle$  such that for some positive integer  $n$ , depending on  $p$ ,  $a_i$  is of order  $p^n$  or  $p^{n+1}$ .

### INTRODUCTION

Let  $M$  be a module over a ring  $R$ . A submodule  $S$  of  $M$  is said to be small in  $M$  if  $S + A \neq M$  for every proper submodule  $A$  of  $M$ . The sum of all small submodules of  $M$  is the Jacobson radical of  $M$  and is denoted by  $\text{Rad } M$ . Also  $\text{Rad } M$  is the intersection of all maximal submodules of  $M$ .

$\mathbf{Z}$  and  $\mathbf{Q}$  will denote the rings of integer and rational numbers respectively. Let  $p$  be a prime number.  $\mathbf{Z}_{p^n}$ ,  $1 \leq n < \infty$ , will denote the cocyclic group of type  $p^n$ . If  $n < \infty$ ,  $\mathbf{Z}_{p^n}$  is a cyclic group of order  $p^n$ , while  $\mathbf{Z}_{p^\infty}$  is the quasi-cyclic group generated by elements  $c_1, c_2, \dots, c_n, \dots$ , such that  $p c_1 = 0, p c_2 = c_1, \dots, p c_{n+1} = c_n, \dots$  (Fuchs 1960).

Let  $G$  be an abelian group.  $\text{Rad } G$  is the Frattini subgroup of  $G$ . For  $a \in G$ ,  $|a|$  will denote the order of the element  $a$ . The  $p$ -primary component of  $G$  will be denoted by  $G_p$ .

For further definitions and basic properties of abelian groups, we refer to Fuchs (1960).

A module  $M$  is called dual continuous (Mohamed & Singh 1977) if it satisfies the following conditions:

- (i) For every submodule  $A$  of  $M$  there exists a decomposition  $M = M_1 \oplus M_2$  such that  $M_1 \subset A$  and  $M_2 \cap A$  is small in  $M$ .
- (ii) Every epimorphism from  $M$  onto a summand of  $M$  splits.

Every quasi-projective module satisfies condition (ii) but not necessarily condition (i). Mohamed & Singh (1977) proved that a ring  $R$  is (semi)perfect if and only if every (finitely generated) quasi-projective  $R$ -module satisfies condition (i). In this paper, we initiate the study of modules satisfying condition (i). Such modules will be called

semi-dual continuous (for short, sd-continuous). We will be interested only in sd-continuous  $\mathbf{Z}$ -modules, that is sd-continuous abelian groups.

## MAIN RESULTS

The following two lemmas are obvious.

*Lemma 1.* A summand of an sd-continuous module is sd-continuous.

*Lemma 2.* A module  $M$  is sd-continuous if and only if every submodule  $A$  of  $M$  is of the form  $A = N \oplus S$  where  $N$  is a summand of  $M$  and  $S$  small in  $M$ .

*Corollary 3.* The  $\mathbf{Z}$ -modules  $\mathbf{Z}$  and  $\mathbf{Q}$  are not sd-continuous.

*Corollary 4.* The  $\mathbf{Z}$ -module  $\mathbf{Z}_{p^n}$  is sd-continuous,  $1 \leq n \leq \infty$ .

Next we prove

*Proposition 5.* Let  $m$  and  $n$  be integers such that  $1 \leq m \leq n \leq \infty$ . If  $n - m > 1$ , then  $G = \mathbf{Z}_{p^m} \oplus \mathbf{Z}_{p^n}$  is not sd-continuous.

*Proof.* Choose  $a \in \mathbf{Z}_{p^m}$  of order  $p^m$  and  $b \in \mathbf{Z}_{p^n}$  of order  $p^{m+1}$ , and let  $K$  be the subgroup of  $G$  generated by  $a + b$ . Then  $K$  is a cyclic group of order  $p^{m+1}$ , and hence contains no non-zero summands of  $G$ . However,  $K$  is not small in  $G$  as  $K$  is not contained in the maximal subgroup  $\langle pa \rangle + \mathbf{Z}_{p^n}$ . Hence  $G$  is not sd-continuous by Lemma 2.

*Proposition 6.* Every sd-continuous abelian group  $G$  is torsion.

*Proof.* Let  $T$  be the torsion subgroup of  $G$ . As  $G$  is sd-continuous,

$$G = T' \oplus F, \quad T' \subset T \text{ and } T \cap F \text{ is small in } G.$$

Suppose that  $T \cap F \neq 0$ . Then as  $T \cap F$  is the torsion subgroup of  $F$ , it contains a non-zero summand of  $F$  by Fuchs (1960, Corollary 24.3). However, this is a contradiction as  $T \cap F$  is small in  $G$ . Hence  $T \cap F = 0$ , and

$$G = T \oplus F.$$

It is clear that  $F$  is torsionfree. We claim that  $F = 0$ . Suppose not. If  $F$  is not reduced, then it contains a summand isomorphic to  $\mathbf{Q}$ . But this would imply that  $\mathbf{Q}$  is sd-continuous by Lemma 1, which is a contradiction to Corollary 3. Thus  $F$  is reduced. Then there exists a prime number  $p$  such that  $pF \neq F$ . Let  $x \in F$  such that  $x \notin pF$ . Then  $\langle x \rangle \not\subset \text{Rad } F$  and so  $\langle x \rangle$  is not small in  $F$ . As  $F$  is sd-continuous by Lemma 1,  $\langle x \rangle$  contains a non-zero summand  $K$  by Lemma 2. Since  $\langle x \rangle \simeq \mathbf{Z}$ ,  $K = \langle x \rangle$ , then  $\mathbf{Z}$  is sd-continuous by Lemma 1 which is again a contradiction to Corollary 3. Therefore  $F = 0$  and the result follows.

*Remark 7.* Let  $G$  be a torsion abelian group. Then  $G = \Sigma \oplus G_p$  where the summation runs over all primes  $p$ . Then using Lemma 1 and the fact that  $\text{Hom}(G_p, G_q) = 0$  for  $p \neq q$ , one can easily see that  $G$  is sd-continuous if and only if each  $G_p$  is sd-continuous.

Using Proposition 6, the above remark shows that it is enough to study sd-continuous abelian  $p$ -groups.

*Lemma 8.* An sd-continuous abelian  $p$ -group  $G$  is either divisible or reduced.

*Proof.*  $G = D \oplus C$  where  $D$  is the maximal divisible subgroup of  $G$  and  $C$  is reduced. Suppose that  $D \neq 0$  and  $C \neq 0$ . Then  $D$  contains a non-zero summand  $U$  isomorphic to  $\mathbf{Z}_{p^\infty}$  and  $C$  contains a non-zero summand  $V$  isomorphic to  $\mathbf{Z}_{p^n}$  for some positive integer  $n$ . Since  $U \oplus V$  is a summand of  $G$ ,  $U \oplus V$  is sd-continuous by Lemma 1. However, this is a contradiction to Proposition 5. Therefore,  $D = 0$  or  $C = 0$ . This completes the proof.

*Theorem 9.* Let  $G$  be a divisible abelian  $p$ -group. Then  $G$  is sd-continuous if and only if  $G$  is a finite direct sum of copies of  $\mathbf{Z}_{p^\infty}$ .

*Proof.* By Fuchs (1960, Theorem 19.1),

$$G = \sum_{i \in I} \oplus A_i$$

where  $A_i \simeq \mathbf{Z}_{p^\infty}$  for all  $i \in I$ . We need only to prove that  $G$  is sd-continuous if and only if the set  $I$  is finite.

Assume that  $I$  is finite. Let  $H$  be a subgroup of  $G$ . Then  $H = D \oplus F$  where  $D$  is the maximal divisible subgroup of  $H$  and  $F$  is reduced. In fact  $F$  is finite and hence small in  $G$ . As  $D$  is a summand of  $G$ , we get  $G$  is sd-continuous by Lemma 2.

Conversely, assume that  $I$  is not finite. Let  $J$  be a countable subset of  $I$ , and let

$$G' = \sum_{j \in J} \oplus A_j \quad .$$

From each  $A_j$  select an element  $x_j$  of order  $p^j$  and let

$$K = \sum_{j \in J} \oplus \langle x_j \rangle \quad .$$

Since  $K$  is unbounded, there exists an epimorphism of  $K$  onto  $A_1$  which extends to a map from  $G'$ . This shows that  $K$  is not small in  $G'$ . Also  $K$ , being reduced, does not contain a non-zero summand of  $G'$ . Hence  $G'$  is not sd-continuous by Lemma 2. But since  $G'$  is a summand of  $G$ , it follows by Lemma 1 that  $G$  is not sd-continuous.

*Theorem 10.* Let  $G$  be a reduced abelian  $p$ -group. Then  $G$  is sd-continuous if and only if there exists a positive integer  $n$  such that  $G$  is a direct sum of cyclic groups of order  $p^n$  or  $p^{n+1}$ .

*Proof.* Let  $G$  be sd-continuous. As  $G$  is a  $p$ -group, it has a basic subgroup say  $B$  (Fuchs 1960, Theorem 29.2). By Lemma 2,  $B = A \oplus S$  where  $A$  is a summand of  $G$  and  $S$  small in  $G$ . Suppose  $S \neq 0$ , then  $S$  contains a non-zero cyclic summand  $K$ . Now  $K$  is pure in  $G$  and hence is a summand of  $G$ . This contradicts that  $S$  is small in  $G$ . Hence  $S = 0$ . Then  $B$  is a summand of  $G$ . As  $G/B$  is divisible and  $G$  is reduced, we get  $G = B$ . Therefore

$$G = \sum_{i \in I} \oplus \langle a_i \rangle$$

such that  $|(a_i)| = p^{\alpha_i}$ . Now, Lemma 1 and Proposition 5 imply that  $|\alpha_i - \alpha_j| \leq 1$  for all  $i, j \in I$ . Thus if  $n$  is the least element in the set  $\{\alpha_i : i \in I\}$ , then any  $\alpha_i$  is  $n$  or  $n + 1$ .

Conversely, let

$$G = \sum_{i \in I} \oplus \langle a_i \rangle$$

such that there exists an integer  $n$  such that for any  $i$ ,  $|(a_i)|$  is  $n$  or  $n + 1$ . Let  $b \in G$  such that  $\langle b \rangle$  is not small in  $G$ . Now

$$b = \lambda_1 a_{i_1} + \dots + \lambda_l a_{i_l} \quad .$$

Let

$$M = \sum_{j=1}^l \oplus \langle a_{i_j} \rangle \quad .$$

Then  $M$  is a summand of  $G$  and  $\langle b \rangle$  is not small in  $M$ . It is clear that for some  $k$ ,  $\langle \lambda_{i_k} a_{i_k} \rangle = \langle a_{i_k} \rangle$ . Among such  $k$ 's there is one for which  $a_{i_k}$  is of largest possible order. It is obvious that

$$M = \langle b \rangle + \sum_{j \neq k} \oplus \langle a_{i_j} \rangle \quad .$$

Since the order of any  $a_{i_j}$  is either  $p^n$  or  $p^{n+1}$ , we get

$$|(b)| = |(\lambda_k a_{i_k})| = |(a_{i_k})| \quad .$$

Then it is immediate that

$$\langle b \rangle \cap \sum_{j \neq k} \oplus \langle a_{i_j} \rangle = 0.$$

Thus  $\langle b \rangle$  is a summand of  $M$ , and hence a summand of  $G$ . This proves that if a subgroup of  $G$  is not small in  $G$ , then it contains a non-zero summand of  $G$ .

Now, let  $H$  be a subgroup of  $G$ . Let  $K$  be a maximal pure subgroup of  $G$  contained in  $H$ . As  $G$  is bounded,  $K$  is a summand of  $G$  (Fuchs 1960, Theorem 24.1). Then  $G = K \oplus L$  for some subgroup  $L$  of  $G$ . If  $H \cap L$  is not small in  $G$ , then  $H \cap L$  contains a non-zero summand  $U$  of  $G$ ; but then  $K \oplus U$  is a pure subgroup of  $G$  contained in  $H$  which contradicts the choice of  $K$ . Thus  $H \cap L$  is small in  $G$ . Therefore,  $G$  is sd-continuous.

The following is an immediate consequence of results (6) through (10).

*Theorem 11.* An abelian group  $G$  is sd-continuous if and only if  $G$  is torsion and for each prime  $p$ , either  $G_p$  is a finite direct sum of copies of  $\mathbf{Z}_{p^\infty}$  or

$$G_p = \sum_{i \in I} \oplus \langle a_i \rangle$$

such that for some positive integer  $n$ , depending on  $p$ ,  $a_i$  is of order  $p^n$  or  $p^{n+1}$ .
